DOI: <https://doi.org/10.28941/pjwsr.v27i4.957>

**ABSTRACT**

Four season's data of floristic structure and biological spectrum of Toormang Valley, Dir lower was explored during 2018-2019. The flora comprised 238 species, 164 genera associated with 60 families. The most prevailing family was Asteraceae with 42 species (17.64%), trailed by Rosaceae 16 (6.72%), Brassicaceae 13(5.46%), Solanaceae 11 (4.62%), Papilionaceae 10 (4.20%), Apiaceae, and Poaceae each with 9 (3.78%), Lamiaceae 8 (3.36%), Boraginaceae, Euphorbiaceae and Moraceae each contributed by 7 species (2.94%), Amaranthaceae and Cucurbitaceae each consisted of 6 species (2.52%), Caryophyllaceae and Chenopodiaceae each with 5 (2.10%) while rest of 23 families contributed by 1 species each (0.42%). The largest genera were *Euphorbia* (6 species), followed by *Sonchus* and *Medicago* (4 species) each. Therophytes were the dominant with 102 species (42.85%), followed by nanophanerophytes with 27 (11.34%), hemicryptophytes with 25 (10.50%), chamaephytes with 20 (8.40%), microphanerophytes with 18(7.56%), megaphanerophytes with 16 (6.72%), geophytes with 15 (6.30%), mesophanerophytes with 14 (5.88%) and parasite with 1 species (0.42%). The observations on leaf size revealed that microphyll was the prevailing class with 73 species (30.67%), followed by mesophyll 69 (28.99%), nanophyll 60 (25.21%), leptophyll 23 (9.66%), macrophyll 8 (3.36%), megaphyll 4 (1.1.68%) and aphyllous with 1 species (0.42%). Simple lamina species 154 while 5 species had spiny lamina shape.

## INTRODUCTION

The Valley is situated in Lower Dir, in the Northwest of Khyber Pakhtunkhwa, Pakistan, and is restricted by a vast series of Koh-e-Hindukush Range. It is situated between 34-37° to 35-7° North latitude and 71-31° to 72-14° East longitudes. The Valley is bounded by Wari in the North, Khall, and Rabat in the West, Laram hills in the South, and Swat in the East. The climate of the Valley is influenced by different ecological and topographic features. The high peaks of the mountains receive snowfall during December, January, and February. The summer is pleasant and short while winter is the harsh season of the year. Agriculture and forests are the main sources of the economy of the indigenous peoples. Flora is the plant species of a given geographical area, whereas vegetation is an ecological term and determines the plant population, size, distribution, and relative importance (RI). (Ali, 2008). Changing environmental situations such as acid rain, soil erosion are alarming threats to flora (Hussain, 2003) while, on the other hand, the floristic configuration is a consideration of phytodiversity, environmental and biotic effects. So, studies on the local flora constantly provide accurate information. Leaf size and life form spectrum are key physiognomic characteristics commonly used in the analysis of vegetation. The biological spectrum determines the micro and macroclimatic conditions of a geographical area (Shimwell, 1971). Many studies have been described therophytes as indicator species of a particular desert-type climate (Samreen et al., 2016). Shah et al. (2013) reported the floristic characteristics of each species from a humid forest situated in an inaccessible area of Pakistan. Hussain et al. (2015) conducted research work on Phytodiversity and ecological physiognomies of the flora of Mastuj, Chitral, and reported the highest percentage of therophytes followed by hemicryptophytes and geophytes. Seraj et al. (2014) determined the Raunkiaerian life form at Asir Mountain of Saudi Arabia and described that

therophytes were the prevailing class followed by chaemophytes. Alsherif et al. (2013) prepared the Raunkierian life form of the Khuliais area, Saudi Arabia, and found that therophytes were the dominant class with the highest percentage of species followed by chaemophytes and hemicryptophytes. Khan et al. (2012) reported that leaf spectra of plants study show the dominance of microphyll followed by nanophyll and leptophyll from Tehsil Takht-e-Nasrati, Karak, Pakistan. The highest percentage of microphyll followed by leptophyll, nanophyll & megaphyll shows that the studied area is under severe biotic stress due to overgrazing and deforestation (Sher and Khan, 2007). The literature study revealed that the research area is virgin regarding its floristic and ecological characteristics.

## MATERIALS AND METHODS

Four season's floristic data of the valley was collected during the year 2018-2019 by walking method (Nazar et al., 2008). Plant specimens were collected, pressed, dried, and mounted on standard herbarium sheets. Plants were identified with the help of Flora of Pakistan (Nasir and Ali, 1970-1989; Ali and Nasir, 1989-1992; Ali and Qaiser, 1995-2015) and verified from the Herbarium, University of Malakand. An alphabetical family-wise list of plants was prepared. The voucher specimens were submitted to the herbarium, Department of Botany, UOM. The tools used during research work were a knife, polythene bags, old newspapers, plant presser, map of the area, notebook, and pencil.

## RESULTS AND DISCUSSION

### Floristic and ecological attributes

The study of the floristic composition of vegetation is crucial for conservation management by providing habitats for wildlife and contributing to the ecologically sustainable management of natural resources (Ahmad and Ehsan, 2012). The flora of the Valley consisted of 238 species, 164 genera from sixty (60) families. It comprised of 53 dicots, 4 monocots, 01 gymnosperm, and 2 pteridophyte families. Pteridophyte had 3 genera (1.82%) while, gymnosperms has 1 genus (0.60%). There were 11

genera of monocots (6.70%) and 149 genera of dicots (90.85%). Leading families were Asteraceae 42 species (17.64%) followed by Rosaceae 16 species (6.72%), Brassicaceae 13 species (5.46%), Solanaceae 11 species (4.62%), Papilionaceae 10 species (4.20%), Apiaceae, and Poaceae each with 9 species (3.78%), followed by Lamiaceae contributed by 8 species (3.36%). Boraginaceae, Euphorbiaceae, and Moraceae each contributed by 7 species (2.94%) while, Amaranthaceae and Cucurbitaceae each consisted of 6 species (2.52%). Caryophyllaceae and Chenopodiaceae had 5 species (2.10%) each, Aspleniaceae and Salicaceae each consists of 4 species (1.68%) while Fagaceae, Oleaceae, Ranunculaceae, Rutaceae, and Urticaceae each contributed by 3 species (1.26%), which is followed by Alliaceae, Asclepiadaceae, Cannabaceae, Ebenaceae, Fumariaceae, Malvaceae, Mimosaceae, Pinaceae, Polygonaceae, and Zygophyllaceae contributed 2 species each (0.84%). The rest of the 23 families contributed by 1 species each (0.42%). (Table 3, Fig. 2) The current reportsmatch with Haq *et al.* (2010) and Ravanbakhsh *et al.* (2014) who describedthat the Asteraceae and Rosaceae are theleading families in their research geographical zone. Similarly, many other authors also documented that Asteraceae was the leading family in their research zones (Ali *et al.*, 2016; Badshah *et al.*, 2016; Inayat *et al.*, 2014; Khan *et al.*, 2011, 2013, 2014; Ganji, 2016; Hussain *et al.*, 2015; Shah *et al.*, 2013; Sher *et al.*, 2014; Ullah and Ullah, 2016). The flora of the research area included wild 196 (82.35%) and cultivated plant species 42 (17.64%). The largest genera were *Euphorbia* (6 species) followed by *Sonchus*, *Chenopodium*, and *Pyrus* (4 species each). There were 5 thorny species (2.10%) and 233 (97.89%) non-thorny species. Based on habitat 115 species (48.31%) were found in dry conditions, 35 species (17.64%) in wet, 42 species (17.64%) in cultivated, and 46 species (19.32%) in both dry and wet conditions. The observations on leaf size revealed that the most prevailing class was microphyll with 73 species (30.67%) followed by mesophyll 69

species (28.99%), nanophyll 60 species (25.21%), leptophyll 23 species (9.66%), macrophyll 8 species (3.36%), megaphyll 4 species (1.1.68%) and aphyllous contributed by 1 species (0.42%). The majority of the species 154 (64.70%) had simple lamina while 5 species have spiny lamina shape. The study area has four distinct seasons with mild summer and harsh winter. The seasonal distinction in flora was verified, with the highest species richness in the summer and spring seasons. Summer flora had 135 species (30.57%), spring with 182 species (30.08%), and autumn had 130 species (21.48%). The lowest species richness 108 (17.35%) were recorded in winter. Our results are strongly correlated with the findings of other researchers such as; Ullah and Badshah (2017) reported the highest number of species in the summer season from Jelar Valley Dir Upper. Similarly, the highest percentage of species were recorded in the spring and summer seasons from Chail Valley Swat and Darazinda D.I. Khan (Ali *et al.*, 2016; Samreen *et al.*, 2016).

### **Biological spectrums**

The phytoclimate determines the biological spectrum of the vegetation of a geographical zone (Khan *et al.*, 2013). The life form of plant species of an area reflectstolerance towards the climatic variations and their genetic makeup (Hussain *et al.*, 2015). The characteristics of the flora and vegetation are reflected by the biological spectra and environmental gradients. Raunkiaer (1934) suggestedclassification of the life form based onthe position of perennating buds during unfavorable environmental conditions. Using this criterion, it was observed that therophytes werethe most abundant life with 102 species (42.85%) followed by nanophanerophytes represented by 27 species (11.34%), hemicryptophyte with 25 species (10.50 %), and Chamaephytes having 20 species (8.40%). Microphanerophytes were represented by 18 species (7.56%), megaphanerophytes with 16 species (6.72 %), geophytes with 15 species (6.30), mesophanerophytes with 14 species (5.88%), and parasite 1 species (0.42) stayed the next prevailing life

forms. (Table 5, Fig. 3). Badshah *et al.* (2016) and Naveed *et al.* (2012) reported that therophytes and nanophanerophytes were the dominant life form classes in their study areas. The dominance of therophytes in this area is due to extreme climatic conditions, overgrazing, and human interference.(Rafay *et al.*, 2013).

### **Seasonal variation**

The current observations show that the highest number of plants species (185) were found in the summer season with therophytes, 64 species (34.59%), the most prevailing life form, followed by nanophanerophytes with 24 (12.97%), hemicryptophytes with 21 species (11.35%), Chamaephytes and microphanerophytes each with 18 species (9.72%), megaphanerophytes with 16 species each 8.64%), mesophanerophytes with 14 species (7.56%), geophytes with 14 species (7.56%), and parasite were represented by 1 species (0.54%). Therophytes were also dominant in the spring season represented by 58 species (32.95%), followed by nanophanerophytes 25 species (14.20%), microphanerophytes 18 species (10.22%), hemicryptophytes 17 species (9.65%), megaphanerophytes 16 species (9.90%), Chamaephytes 15 species (8.52%), mesophanerophytes 14 species (7.95%), geophytes 12 species (6.81%), and parasite represented by 1 species (0.56%). During Autumn therophytes consist of 31 species (24.03%), nanophanerophytes 23 species (17.82%), microphanerophytes 18 species (13.95%), megaphanerophytes 16 species (12.40%), mesophanerophytes 14 species (11.11%), hemicryptophytes 13 species (10.07%), Chamaephytes 11 species (8.52%), geophytes 2 species (1.55%), and parasite include 1 species (0.77%), while, the lowest numbers of species were noted in winter. (Table 1, Fig. 4). Our current investigations are supported by Badshah *et al.* (2016) who described that therophytes were the highest in number during spring and summer seasons from Parachinar, Kurram Agency, Pakistan.

### **Leaf size spectrum**

The observation of the leaf size explains the plant's biological processes and their communities. Leaf size and biological spectra are used in the classification and association of communities (Ali *et al.*, 2016). It is useful for the understanding of physiological processes of plant species and their communities (Oosting, 1956) as well as the leaf-sized classes are important for studying the associations. Our findings on leaf size exhibited that macrophyll was the most leading class with 73 species (30.68%), followed by mesophyll 69 species (28.99%), nanophyll 60 species (25.22%), leptophyll 23 species (9.66%), macrophyll 8 species (1.26%), megaphyll 4 species (1.68%), and aphyllous comprised by 1 species of *Cuscuta reflexa* Roxb, (0.42%). (Table 5, Fig.7). Our results are in line with the findings of Khan *et al.* (2013), Shah *et al.* (2013), Khan *et al.* (2011), Amjad. (2012) and Khan *et al.* (2014).

### **Seasonal variation**

In summer, mesophyll was the prevailing leaf size class contributed by 58 species (31.35%), followed by microphyll 55 species (29.72%), nanophyll 48 species (25.94%), leptophyll 18 species (9.72%), macrophyll 4 species (2.16%), megaphyll and aphyllous by 1 species each (0.54%). In spring microphyll were dominant form consisted of 53 species (30.81%), followed by mesophyll 49 species (28.48%), nanophyll 44 species (25.58%), leptophyll 13 species (7.55%), macrophyll 8 species (4.65%), megaphyll 4 species (2.32%), and aphyllous contributed by 1 species (0.58%). In autumn mesophyll was the dominant form consisted of 45 species (34.88%), followed by nanophyll 33 species (25.58%), microphyll 31 species (24.03%), leptophyll 14 species (10.85%), macrophyll 3 species (2.32%), megaphyll 2 species (1.55%), and aphyllous contributed by 1 species (0.77%). While mesophyll was also dominant in winter contributed by 37 species (33.94%), followed by microphyll with 32 species (29.35%), nanophyll with 24 species (22.01%), leptophyll with 8 species (7.33%), macrophyll with 6 species (5.50%),

megaphyll and aphyllous contributed by 1 species each (0.91%). (Table 2, Fig. 5).

### **Lamina shape**

The shape of leaf lamina of different plant species revealed that 154 species (64.70%) have simple lamina shape, followed by compound and dissected lamina each have 37 species (15.54%), spiny 5 species (2.10%), needles lamina shape consist 2 species (0.84%), while in 3 species lamina shape is absent. (Table 5, Fig. 6) The lamina shapes of the plant species were also reported from Jelar Valley, Upper Dir(Ullah and Badshah., 2017), from Darazinda DI. Khan (Samreen et al., 2016) and from Chail Valley, Swat. (Ali et al., 2016).

### **Habit and Habitat**

Among the flora, herbs were dominant comprises 167 species (70.16%), followed by shrub 48 species (18.06%) and trees were contributed by 28 species (11.76%). (Table 5, Fig. 9) The highest numbers of 115 species (48.31%) were found growing in dry conditions, followed by 46 species (19.32%) growing in both dry and wet conditions, 42 species were found growing on agricultural land, while 35 species were found growing on the wetland. (Table 5, Fig. 8). The research area is under high anthropogenic pressure as indigenous peoples rely on fuelwood and forest timber. Ultimately, this rapid deforestation resulting indisturbing themico and micro-habitats (Ali et al., 2016).

### **Conclusion**

The present results revealed that the flora of the valley consisted of 238 species, 164 genera from 60 families. It included 53 dicots, 04 monocot families, 01 family of Gymnosperms, and 2 Pteridophyte families. Pteridophyte had 3 genera (1.82%) while; Gymnosperms had 01 genus (0.60%). There were 11 genera of monocots (6.70%) and 149 genera of dicots (90.85%). Leading families were Asteraceae 42 species (17.64%), Rosaceae 16 species (6.72%), Brassicaceae 13 species (5.46%), Solanaceae 11 species (4.62%), and Papilionaceae 10 species (4.20%). The largest genera regarding

the number were *Euphorbia* (6 species), *Sonchus*, *Chenopodium*, *Medicago*, and *Pyrus* (4 species each). The dominant life form based on species richness was therophytes with 102 species (42.85%), followed by nanophanerophytes with 27 species (11.34%). Leaf size spectra showed that the macrophyll was the most dominant leaf size classwith 73 species (30.67%), followed by mesophyll 69 species (28.99%). The current study provides baseline observations and information of Toormang flora and further study is recommended for the exploration of quantitative analysis of the vegetation.
